

# Slit scan + TDS @PITZ, first results

- > Setup: EMSY2 slit, 5 m drift length to PST.Scr1 with TDS inbetween
- > Manual slit scan in order to average 10 images at each slit position for higher signal-to-noise ratio (LYSO n/a yet)
- > Matlab tools written for offline image filtering and analysis
  - Main idea: cut beamlet images in vertical slices and analyse those separately
- > 4 scans done so far: 500 pC@BSA12 and BSA15, 1nC@BSA15
  - 11-14 slit positions, 50  $\mu\text{m}$  slit
- > Also fastscans w/o TDS done

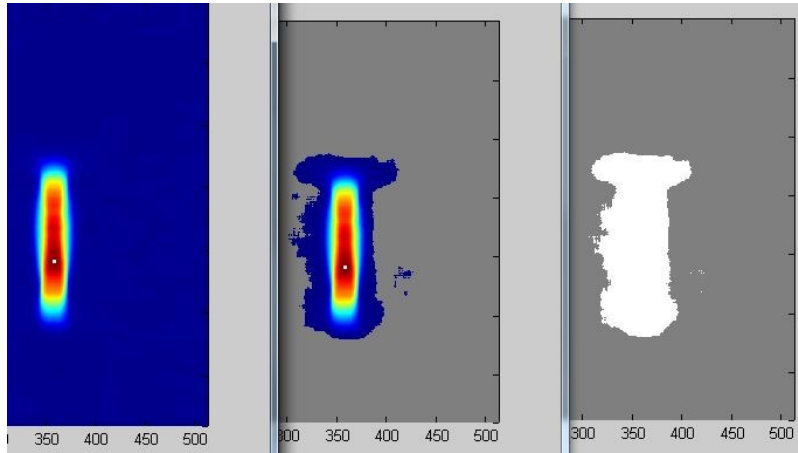

„Semi-manual“ image filtering

Filter settings, thresholds and noise cut options can and should be adjusted for each (averaged) image

Phase space construction & SLEM analysis

GUI shows phase space, SLEM & mismatch parameter, and the filtered images

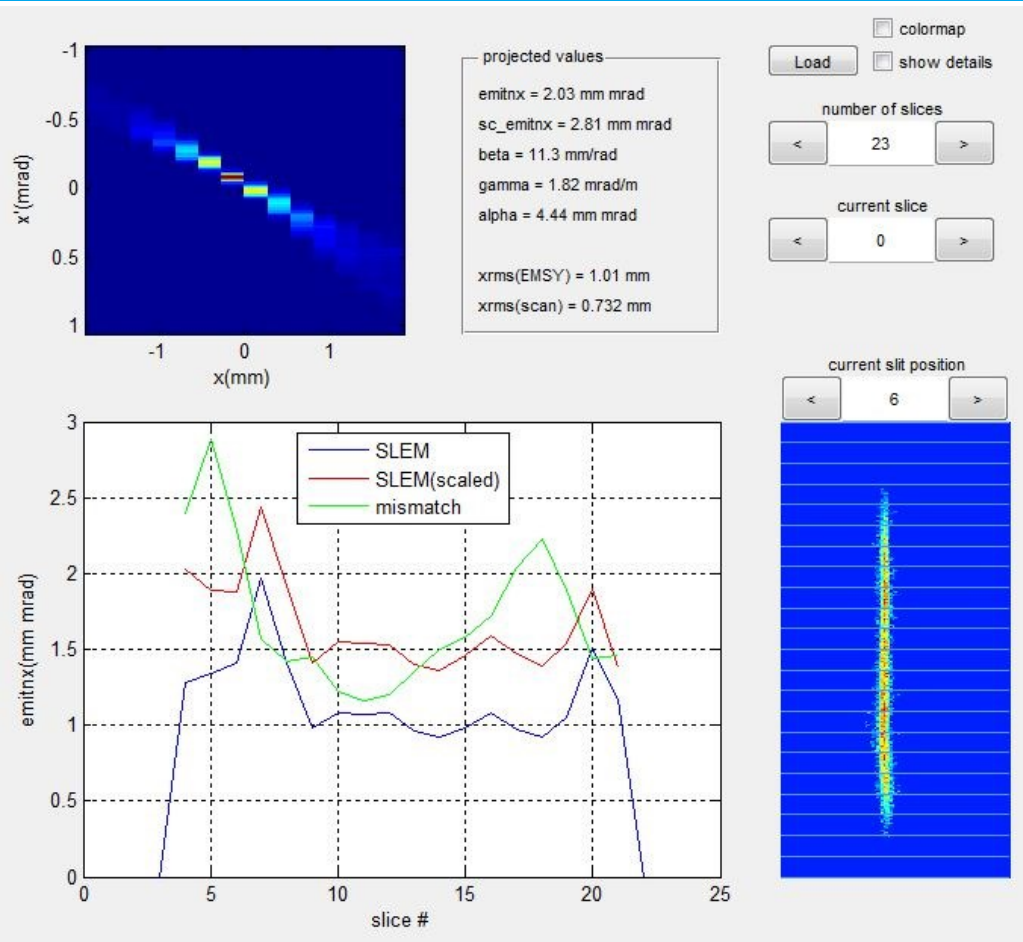

Creating MOI

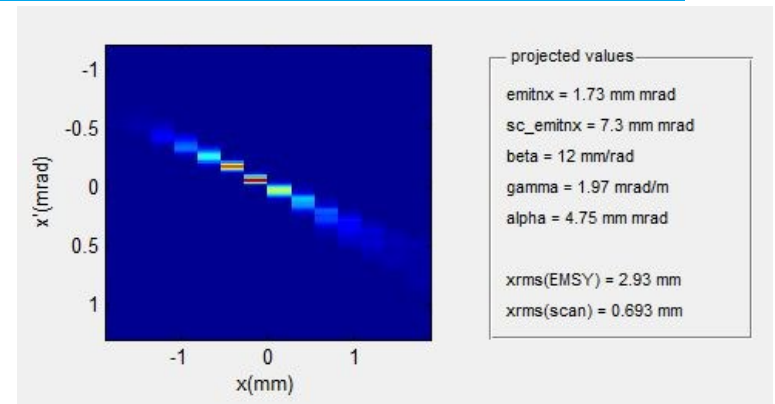

averaging > applying MOI > noise cut

- „scaled“: emitnx scaled by  $x_{rms}(EMSY)/x_{rms}(phasespace)$
- SLEM is not scaled
- Emittances are in [mm mrad], other parameters in SI units
- (side note: TWISS units in emcalc screenshots are wrong)
- Red circles are hard-to-believe numbers...probably sth. went wrong

- > **First results look very promising**, despite occasionally large discrepancies
- > SLEM largely independent of number of slices (10-30)
- > Projected phase space and  $\alpha\beta\gamma$ -values are pretty similar to fastscan results for almost every measurement
- > Emittance values show some larger discrepancies, partly because of EMSY-scaling
  - EMSY-scaling is known to jitter on the order of 10%
  - In one case (1nC), EMSY analysis by fastscan gave 20% difference when switching on TDS (should be zero)
  - In one case, EMSY analysis by fastscan yielded 1.3 mm while both manual analysis of the same file and the VC analysis said 1.7 mm
- > Other important systematic issues:
  - Significant smaller scan range in manual scans (see p.7)
  - Lower intensity with TDS on
  - Large slit size, not taken into account by the analysis
  - Only ~10 different slit positions
