

# Acousto-optic Modulator (AOM) as Laser Pulse Picker

First Experiences at PITZ

Matthias Gross, Guido Klemz

AOM as Pulse Picker

PITZ Physics Seminar, 08. Dec. 2011

# Contents

- Motivation
- Principle: The Acousto-Optic Effect
- Properties of an Acousto-Optic Modulator (AOM)
- Setup at PITZ
- First Results
- Next Steps
- Summary

# Motivation

- > Critical part of photocathode laser system: frequency quadrupling. Wavelength of laser pulses is converted from infrared to ultraviolet (at PITZ: 1030nm  $\rightarrow$  257.5nm) in two steps with nonlinear crystals – LBO and BBO
- > BBO crystal (2<sup>nd</sup> step – 515nm  $\rightarrow$  257.5nm) absorbs a tiny fraction of UV light – significantly enough that effects have been seen at PITZ and FLASH
  - Absorption leads to local increase of temperature which changes the properties of the frequency conversion
- > PITZ
  - Difference of “cold OSS” and “warm OSS”
  - Variations of bunch charge over pulse train
- > FLASH
  - Variation of beam arrival time over pulse train

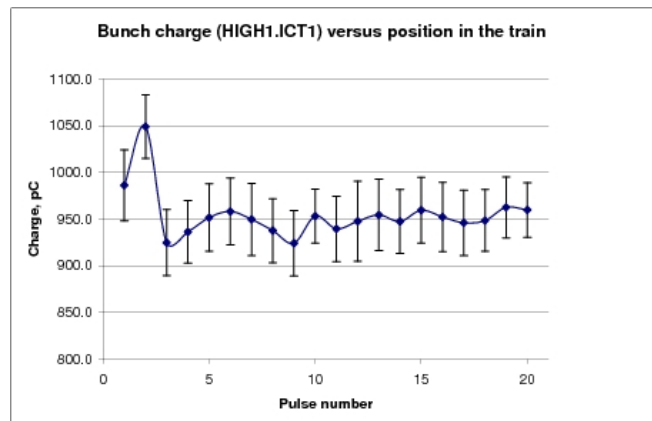

# Experimental Evidences for BBO Crystal Warming at PITZ

- OSS: Difference of pulse length and form directly after starting and after waiting a few minutes (measured 05.05.2011M)

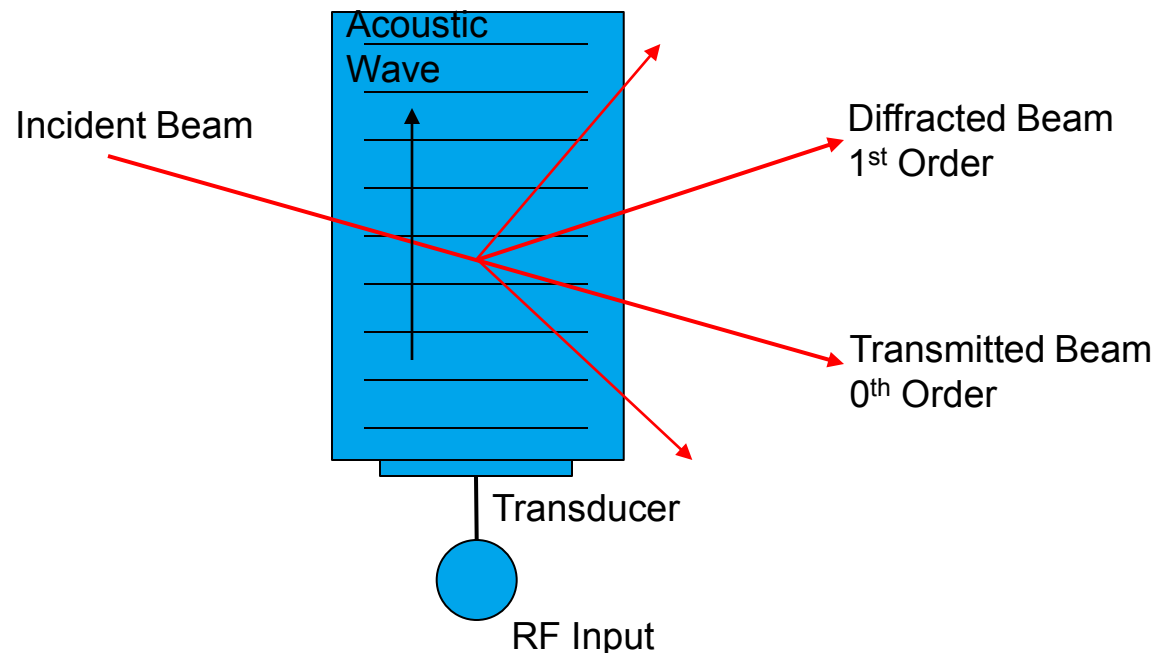

- Bunch charge along pulse train (measured 04.05.2011M)

# The Acousto-Optic Modulator (AOM)

- Possible solution: cw pulse train conversion into UV, then definition of pulse trains with UV pulse picker → stable temperature of BBO crystal
  - Important: pulse picker must not show same affect as BBO crystal!
- Candidate for pulse picker: Acousto-Optic Modulator (AOM)
  - Principle: Diffraction of laser beam at acoustic wave

# Comparison of available AOMs

	Crystal Technologies via EQ Photonics: 3200-1220	A-A Optoelectronics via Pegasus Optik: MQ200-B30A1.5-244.266-Br	Gooch & Housego: 35110-2-244-BR (APE: OA99)	Brimrose via Laser2000: FSPP-250-16-BR-257	
Material	SiO <sub>2</sub> (Quartz)	SiO <sub>2</sub> (UV grade fused silica)	SiO <sub>2</sub> (KrF grade fused silica)	SiO <sub>2</sub> (UV grade fused silica)	
Wavelength	257nm	244-266nm	244-260nm	257nm	
Aperture	0.25mm diameter	1.5mm x 2mm	2mm diameter	0.3mm diameter	
Center Frequency	200MHz	200MHz	110MHz	250MHz	
Rise time (10%-90%)	143ns/mm beam diameter	110ns/mm beam diameter 10ns min.	110ns/mm beam diameter 10 ns min.	34nm min.	
Contrast ratio DC	1000:1	2000:1	1000:1	>1000:1	
Contrast ratio 1MHz	same	same	same	? (same)	
Diffraction efficiency	75%	>70% over range >85% @ 257nm	>70%	50%	
Insertion loss	<5%	<5%	<1%	<2%

> Gooch&Housego AOM was bought in August 2011 (funded by FLASH)

# Some Checks

- > Used beam: 1<sup>st</sup> order (highest contrast – ideally no power with RF off)
  - Total loss:  $(1 - \text{insertion loss}) * \text{diffraction efficiency} \rightarrow$  around 20% at 257nm
- > 1<sup>st</sup> order is frequency shifted
  - $\Delta\lambda = \frac{\lambda}{c} \Delta f$      $\Delta f$ : Center frequency (110MHz)  $\rightarrow \Delta\lambda < 0.1\text{pm}$  – negligible
- > Progress of acoustic wave front during pulse duration (20 ps)
  - $0.12\mu\text{m} \ll$  beam diameter (1mm)  $\rightarrow$  optical pulse sees essentially fixed reflector
- > Pointing stability
  - $\Delta\Theta \approx \lambda \frac{\Delta f}{V_a}$      $\Delta f$ : Frequency uncertainty;  $V_a$ : acoustic velocity ( $\approx 6000\text{m/s}$  for  $\text{SiO}_2$ )  
↳ e.g. 1Hz  $\rightarrow \Delta\Theta \approx 5 \cdot 10^{-11}$  rad (1nm at 20m distance) – negligible
- > Separation of diffraction orders
  - Angular separation: Equation as above with  $\Delta f$ : Center frequency (110MHz)
  - Distance to spatial separation of 0<sup>th</sup> and 1<sup>st</sup> order by 5mm:  $\approx 2.10\text{m}$

# AOM setup at PITZ

- From Gooch & Housego: AOM + Driver + stage
- Guido Klemz: Buildup of electronic box including driver and interface to PITZ laser, e.g. trigger for synchronization
- Optical setup on laser table (switchable AOM mode)

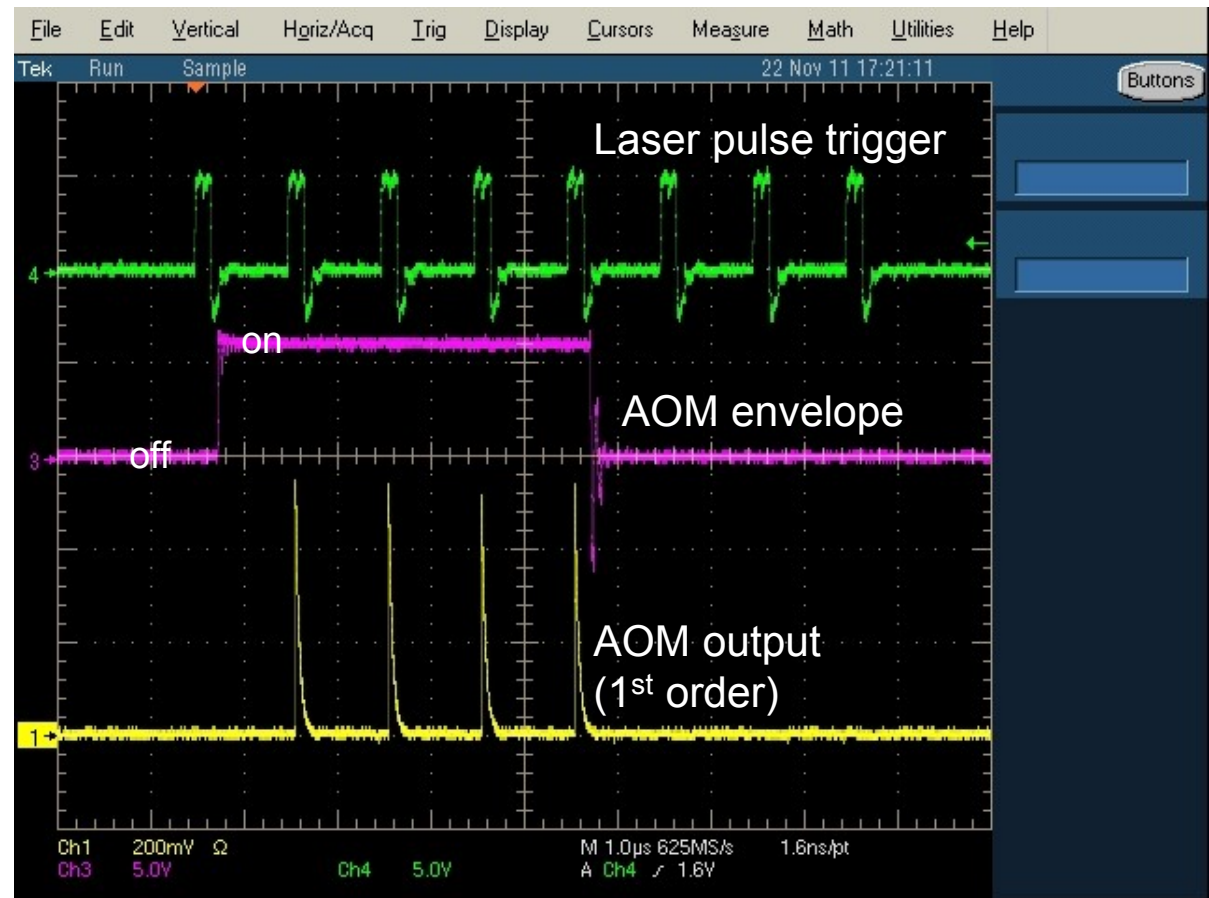

# First Results (1)

## > Electronics: Currently 2 standard modes

- AOM on when laser pulses present
- AOM envelope adjustable

## > Fast switching – pulse to pulse

## > High contrast ratio (at least 500:1)

# First Results (2)

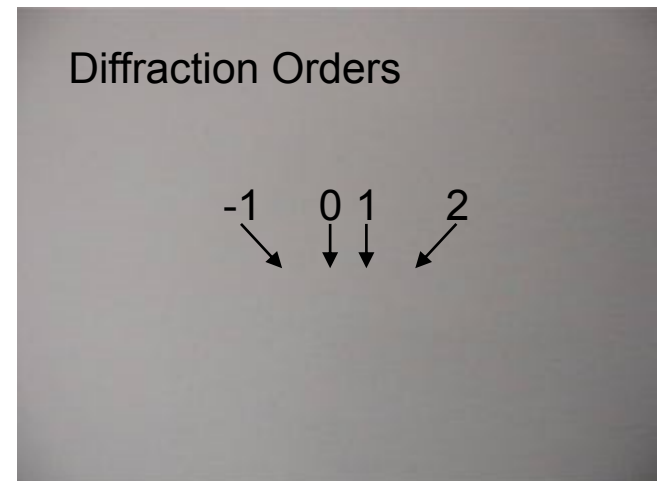

## > Measurement: Relative power in diffraction orders

Order	-1	0	+1	+2
RF off	0%	100%	0%	0%
RF on	2%	8%	79%	8%

## > Measured diffraction efficiency $\approx 80\%$

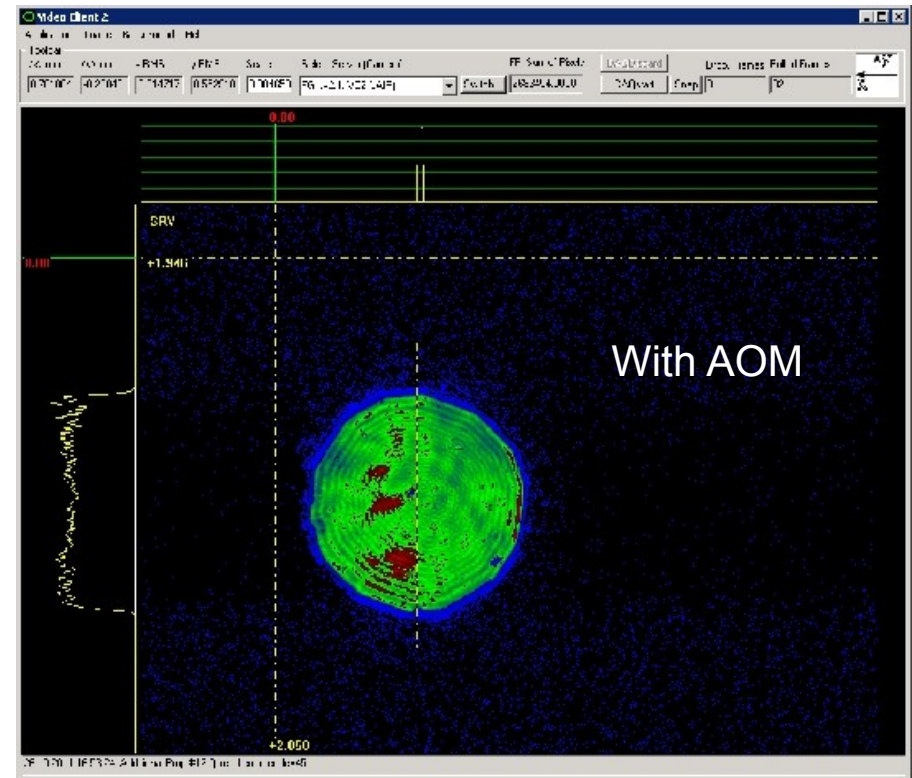

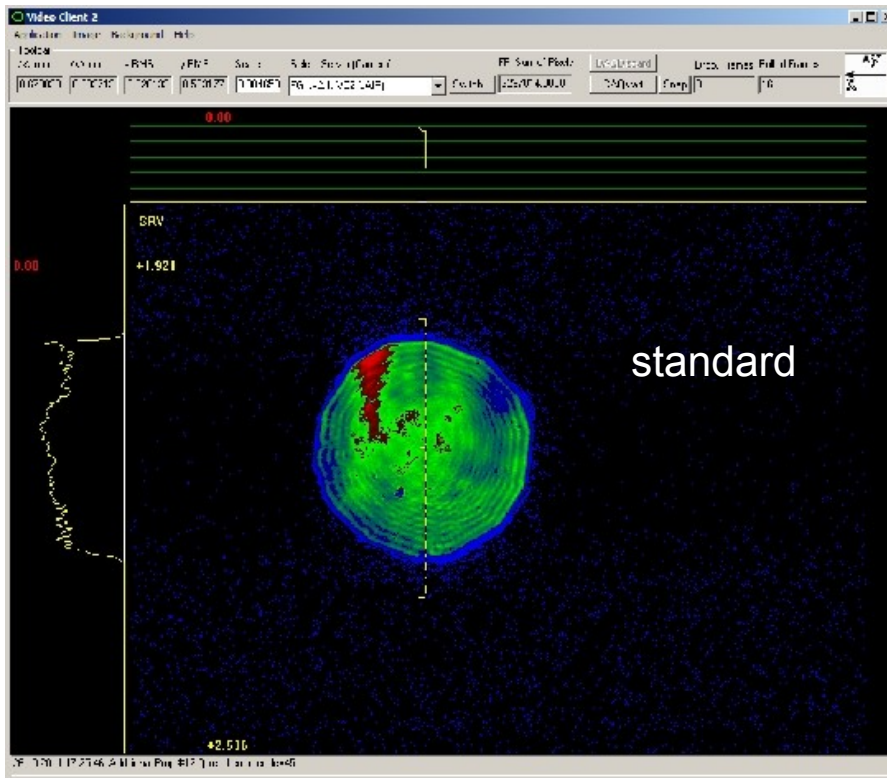

## > With RF on almost all power in 1<sup>st</sup> order and next neighbor orders

- $\text{SiO}_2$  has low optical losses in UV (<0.1% for AOM) should bring improvement to original problem

# First Results (3)

## ➤ Measurement with VC2 (measured 26.10.2011A)

## ➤ No visible influence of AOM to lateral profile

# Next steps

- > Influence on temporal pulse profile (OSS)
- > Total efficiency (energy meter)
- > Determine extinction ratio (PMT, PCO camera)
- > Energy/position-jitter over pulse train (PMT+PCO/VC2)
  - Synchronization of RF driver for acoustic wave to master oscillator – fix phase of acoustic wave when laser pulse arrives (available: 108MHz)
- > Integration into PITZ  $\mu$ s timing system (GUI)
- > Experiments with electron beam
  - Extinction ratio etc. as above
  - Bunch charge along pulse train
  - Emittance measurements?

# Summary

- > Photocathode laser: Influence of BBO conversion crystal warming on properties of electron bunches (Charge, arrival time etc.)
  - Seen at PITZ and FLASH
- > Possible solution: UV Acousto-Optic Modulator (AOM) as pulse picker
- > AOM was bought and is being tested at PITZ
- > First results:
  - Fast enough to pick single pulses with high contrast ratio
  - Low loss / high diffraction efficiency
  - No visible influence on lateral profile
- > Next: More experiments at PITZ, later FLASH(?)
